

Problem Statement - Stock Market Volume Prediction using Machine Learning

Stock market trading volume is a critical indicator of market activity and investor sentiment. Accurately predicting trading volume helps traders, investors, and financial institutions make informed decisions, manage risk, and optimize trading strategies. However, stock volume data is highly volatile, influenced by multiple factors like price movements, market trends, and historical patterns. Traditional methods fail to capture these complex non-linear relationships accurately. The goal is to develop a Machine Learning model that analyzes historical stock data to predict future trading volume with high accuracy, enabling smarter and data-driven financial decisions.
